

RTO probe: canary-write gaps around a process kill

source: 20260905T213941Z_p4-chaos-dead

claim: a 869 ms gap in served writes occurred 40.2s after the fault, but it is NOT distinguishable from this probe's own tail: gaps over the healthy 95th percentile occurred 30 times after the fault against 72.1 expected from the pre-fault rate. Do not quote it as a recovery time -- the post-fault window is simply longer, so its maximum is larger for that reason alone
